

MALIGNANT COMMENTS CLASSIFICATION PROJECT

Submitted by ASHWATHY A ARAVIND

ACKNOWLEDGMENT

The project entitled "MALIGNANT COMMENTS CLASSIFICATION" is done by me during my internship with Flip Robo Technologies. I am grateful to Data Trained and Flip Robo Technologies for their guidance during this project.

INTRODUCTION

Conceptual Background of the Domain Problem

The proliferation of social media enables people to express their opinions widely online. However, at the same time, this has resulted in the emergence of conflict and hate, making online environments uninviting for users. Although researchers have found that hate is a problem across multiple platforms, there is a lack of models for online hate detection.

Online hate, described as abusive language, aggression, cyberbullying, hatefulness and many others has been identified as a major threat on online social media platforms. Social media platforms are the most prominent grounds for such toxic behaviour.

There has been a remarkable increase in the cases of cyberbullying and trolls on various social media platforms. Many celebrities and influences are facing backlashes from people and have to come across hateful and offensive comments. This can take a toll on anyone and affect them mentally leading to depression, mental illness, self-hatred and suicidal thoughts.

Internet comments are bastions of hatred and vitriol. While online anonymity has provided a new outlet for aggression and hate speech, machine learning can be used to fight it. The problem we sought to solve was the tagging of internet comments that are aggressive towards other users. This means that insults to third parties such as celebrities will be tagged as unoffensive, but "u are an idiot" is clearly offensive.

PROBLEM STATEMENT:

Our goal is to build a prototype of online hate and abuse comment classifier which can used to classify hate and offensive comments so that it can be controlled and restricted from spreading hatred and cyberbullying.

Analytical Problem Framing

Mathematical/ Analytical Modeling of the Problem

- With continuous increase in available data, there is a pressing need to organize it and modern classification problems often involve the prediction of multiple labels simultaneously associated with a single instance. Known as Multi-Label Classification, it is one such task which is omnipresent in many real world problems. In this project also, we have multi-label classification problem.
- We have used Tf-Idf Vectorizer to vectorize the words in our dataset. TF-IDF is an
 abbreviation for Term Frequency Inverse Document Frequency. This is very
 common algorithm to transform text into a meaningful representation of numbers
 which is used to fit machine algorithm for prediction. It is very important for
 tuning performance on NLP projects.
- The TF-IDF score for the word t in the document d from the document set D is calculated as follows:

$$tfidf(t, d, D) = tf(t, d) \cdot idf(t, D)$$

• Where:

$$tf(t, d) = log(1 + freq(t, d))$$

$$idf(t, D) = log(\frac{N}{count(d \in D: t \in d)})$$

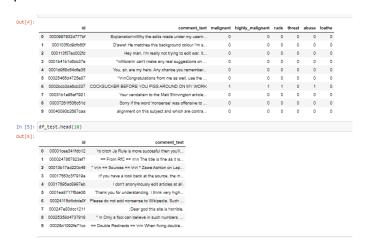

Data Sources and their formats

- The data set contains the training set, which has approximately 1,59,000 samples and the test set which contains nearly 1,53,000 samples. All the data samples contain 8 fields which includes 'ld', 'Comments', 'Malignant', 'Highly malignant', 'Rude', 'Threat', 'Abuse' and 'Loathe'.
- The label can be either 0 or 1, where 0 denotes a NO while 1 denotes a YES. There are various comments which have multiple labels. The first attribute is a unique ID associated with each comment.

The data set includes:

- Malignant: It is the Label column, which includes values 0 and 1, denoting if the comment is malignant or not.
- Highly Malignant: It denotes comments that are highly malignant and hurtful.
- **Rude:** It denotes comments that are very rude and offensive.
- Threat: It contains indication of the comments that are giving any threat to someone.
- **Abuse:** It is for comments that are abusive in nature.
- Loathe: It describes the comments which are hateful and loathing in nature.
- **ID:** It includes unique Ids associated with each comment text given.
- **Comment text:** This column contains the comments extracted from various social media platforms.

The sample data for the reference is as shown below:

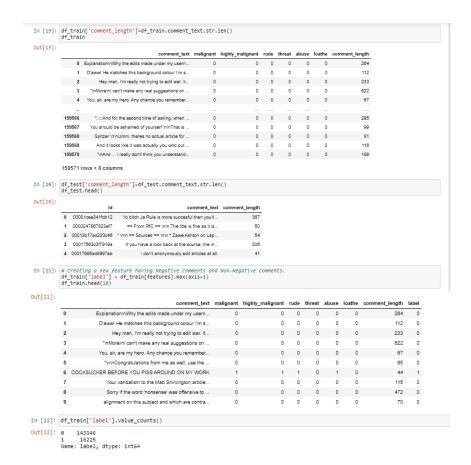

• Then we further checked more about data using info, shapes using .shape, columns using .columns(),null values using .isnull. .sum().sum(), and further visualize it through heatmap as follows:

• Then we perform Exploratory Data Analysis(EDA) as follows:

 Next we will be using a function to filter using POS tagging. Also, all the preprocessing steps needed to clean the data.

```
In [24]:

def get_pos(pos_tag):
    if pos_tag.startswith(')'):
        return wordet.NOLN("):
        return wordet.NOLN("):

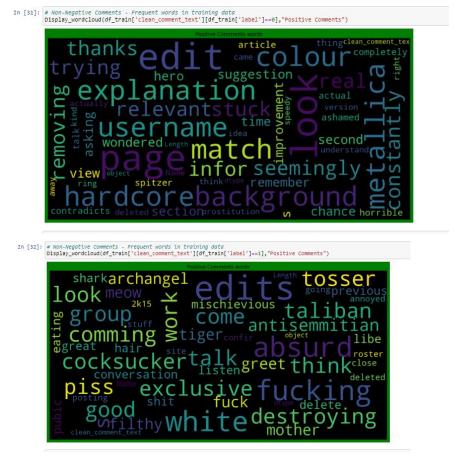

In [25]:

# Function for data cleaning...
def Processed_data(coments):
        * Appliace email addresses with 'email'
        comments=result("\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\="\emails"\=\emails"\=\emails"\=\emails \emails \ema
```

 After performing all the above steps and also adding a new feature to check new comment length after cleaning, our dataset would look as follows:

 We have also observed most frequent words in positive and negative comments through word-cloud:

• Then we have checked distribution of comment length before and after cleaning.

Preparing Data For Modelling

• We are using TF-IDF vectorizer for vectorizing the words.

```
In [35]: # TF-IDF(term frequency-inverse document frequency) vectorizer
def Tf_idf_train(text):
    tfid = Tfidfvectorizer(min_df=3,smooth_idf=False)
    return tfid.fit_transform(text)

In [36]: # Let's define x, y for modelling
    x=Tf_idf_train(df_train['clean_comment_text'])
    x.shape

Out[36]: (159571, 43194)

In [37]: # For y
    y = df_train['label'].values
    y.shape

Out[37]: (159571,)
```

MODEL BUILDING

```
In [38]: # Importing useful libraries for model training

from sklearn.linear_model import LogisticRegression
from sklearn.naive_Dayes import NultinomialNB
from sklearn.nere import DecisionTreceLassifier
from sklearn.linear_model import LogisticRegression
from sklearn.su import SVC
from sklearn.naipenbors import KNeighborsClassifier

# Model selection libraries...
from sklearn.model_selection import cross_val_score, cross_val_predict, train_test_split
from sklearn.model_selection import decisionsport.

# Importing some metrics we can use to evaluate our model performance...
from sklearn.metrics import accuracy_score, classification_report, confusion_matrix
from sklearn.metrics import roc_auc_score, roc_curve, auc
from sklearn.metrics import roc_auc_score, roc_curve, auc
from sklearn.metrics import precision_score, recall_score, fl_score

In [39]: #splitting the data into training and testing
x_train,x_test,y_train,y_test=train_test_split(x,y,random_state=42,test_size=0.30,stratify=y)

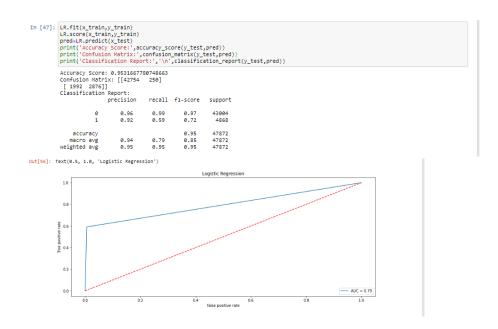

In [40]: # creating instances for different Classifiers

LR=LogisticRegression()
NMB=NultinomialNB()
OT_DecisionTrecelassifier()
XN=NultingSphorsClassifier()
XN=NultingSphorsClassifier()
XN=NultingSphorsClassifier()
XN=NultingSphorsClassifier()
NN=NultingSphorsClassifier()
Nn=NultingSphorsCl
```

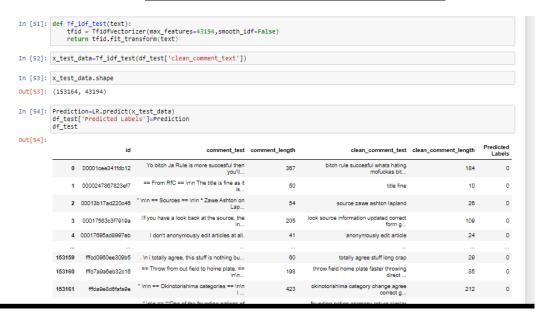

We obtained following results after training the model on various algorithms:

```
*********** MultinomialNB ************
MultinomialNB()
Accuracy_score= 0.9354737633689839

   roc_auc_score= 0.6214955391587276
```

 Since the dataset was too large it took me around 9-10 hours to get these results for these algorithms. Hence I had to interrupt the kernel and proceed with available results. Out of all the algorithms, Logistic Regression was giving best score. Also, its cross validation score was also satisfactory. Its ROC_AUC curve is as shown:

PREDICTING TEST DATASET

CONCLUSION

- We have got Logistic Regression as best model since it's giving us good result and other metrics are also satisfactory.
- Using Logistic Regression as our final algorithm we have predicted the values for test dataset and it's also working well and is able to differentiate/predict negative comments and non-negative (good) comments.
